# Clustering of auxiliary data

- Every datapoint can be member in one of K clusters.
- Use clustering approach to determine cluster membership

$$oldsymbol{\pi}_n = \{\pi_{n,1}, \dots, \pi_{n,K}\}$$
 where  $\sum_{k=1}^K \pi_{n,k} = 1$ 

- ∢ 🗇 እ

#### Robust noise model

Remember: standard robust noise model, accounting for outliers

$$p(y_n \mid f_n) = \pi_{ok} \mathcal{N}\left(y_n \mid f_n, \sigma^2\right) + (1 - \pi_{ok}) \mathcal{N}\left(y_n \mid f_n, \sigma^2_\infty\right)$$

Here: clustering results (auxiliaries S) encode useful information.

Generalize likelihood K noise components, one for each cluster and use data-specific mixture probabilities π<sub>n</sub>

$$p(y_n \mid f_n) = \sum_{k=1}^{K} \pi_{k,n} \mathcal{N}\left(y_n \mid f_n, \sigma_k^2\right)$$

#### Robust noise model

Remember: standard robust noise model, accounting for outliers

$$p(y_n \mid f_n) = \pi_{ok} \mathcal{N}\left(y_n \mid f_n, \sigma^2\right) + (1 - \pi_{ok}) \mathcal{N}\left(y_n \mid f_n, \sigma^2_\infty\right)$$

► Here: clustering results (auxiliaries S) encode useful information.

Generalize likelihood K noise components, one for each cluster and use data-specific mixture probabilities π<sub>n</sub>

$$p(y_n \mid f_n) = \sum_{k=1}^{K} \pi_{k,n} \mathcal{N}\left(y_n \mid f_n, \sigma_k^2\right)$$

#### Robust noise model

Remember: standard robust noise model, accounting for outliers

$$p(y_n \mid f_n) = \pi_{ok} \mathcal{N}\left(y_n \mid f_n, \sigma^2\right) + (1 - \pi_{ok}) \mathcal{N}\left(y_n \mid f_n, \sigma^2_\infty\right)$$

Generalize likelihood K noise components, one for each cluster and use data-specific mixture probabilities π<sub>n</sub>

$$p(y_n \mid f_n) = \sum_{k=1}^{K} \pi_{k,n} \mathcal{N}\left(y_n \mid f_n, \sigma_k^2\right)$$

Results

# Regression for Heart Data

Single data set

- Clustering color-coded and Hinton diagrams
  - Three clusters

     g,b,r-values
     for responsibilities
- Noise parameters  $\{\sigma_c\}_{c=1}^3$ optimised along with other hyper parameters

Tübingen 11

Results

# Regression for Heart Data

- Two sensors for one heart
- GPs overlap well within error-bars
- Lower panel: difference plot and error bars

O. Stegle & K. Borgwardt

Tübingen 12

# Fill-in test

- Evaluate predictive performance to benchmark alternative models
- Fill-in test:
  - Model is trained on a subset of the data to predict the remainder.
  - Log probability as criteria rewards models with appropriately sized error bars.

Image: A math a math

#### Results

# Block size 1 minute

# Block size 1 minute

- 5 different models compared
  - (i) baseline
  - (ii) GP with ks
  - (iii) GP with ks + kl
  - (iv) as (iii) but with Tlost threshold noise model
  - (v) as (iv) but with full robust noise model

#### Results

# Block size 60 minute

# Block size 60 minutes

- 5 different models compared
  - (i) baseline
  - (ii) GP with ks
  - (iii) GP with ks + kl
  - (iv) as (iii) but with Tlost threshold noise model
  - (v) as (iv) but with full robust noise model
- Larger blocks removed rewards long range covariance

# Differential Gene Expression

- An important goal is the identification of differentially expressed genes.
  - Identification of involved regulatory components.
  - Uncovering parts of the biological network.

- ∢ ⊢⊒ →

# Differential Gene Expression

- An important goal is the identification of differentially expressed genes.
  - Identification of involved regulatory components.
  - Uncovering parts of the biological network.

# Differential Gene Expression in Time Series Time Series

### • The response to external stimuli is a dynamic process.

• Hence the response should be studied as a function of time.
# Differential Gene Expression in Time Series Time Series

- The response to external stimuli is a dynamic process.
- Hence the response should be studied as a function of time.

O. Stegle & K. Borgwardt

### Differential Gene Expression in Time Series Challenges

- ► Time series expression profiles vary smoothly over time.
- Noisy observations outliers.
- Multiple replicates.
- Few observations.
- ► Temporal patterns (intervals) of differential gene expression.

#### Gaussian process Model Model comparison

#### The basic idea – a comparison of two models:

The *shared* model: Expression levels are explained by a single process.
 The *independent* model: Expression levels are explained by two separate processes.

(日) (同) (三) (三)

#### Smooth Time-local GPTwoSample Example Results

Detecting Transition Points in *Arabidopsis* Microarray Time Series Start/Stop Times

- Studying the temporal distribution of differential expression across genes.
- Considered were the top 6000 differentially expressed genes.
- Differential expression appears to occur in two waves with start times at 20h an 25h after infection.
- Only very few genes stop differential behavior within the measured time interval.

Distribution of differential start/stop time

- The functional proteins and their concentration levels remain unobserved.
- Motivation: Infer the hidden protein concentrations?

#### Motivation

- Microarray technologies allow to measure mRNA levels.
- The functional proteins and their concentration levels remain unobserved.
- Motivation: Infer the hidden protein concentrations?

#### A single gene model

The change in gene expression abundance y<sub>i</sub> for a gene i is approximately described by a differential equation model of the form

$$\frac{\mathrm{d}y_i(t)}{\mathrm{d}t} = B_i + S_i f(t) - D_i y_i(t)$$

- f(t) regulatory transcription factor.
- ► *B<sub>i</sub>* basal transcription rate.
- ► S<sub>i</sub> sensitivity of the gene to the transcription factor.
- $D_i$  decay rate of the mRNA.
- Goal: infer the unobserved activation f(t) from mRNA measurements of multiple target genes.

#### A single gene model

The change in gene expression abundance y<sub>i</sub> for a gene i is approximately described by a differential equation model of the form

$$\frac{\mathrm{d}y_i(t)}{\mathrm{d}t} = B_i + S_i f(t) - D_i y_i(t)$$

- f(t) regulatory transcription factor.
- ► *B<sub>i</sub>* basal transcription rate.
- ► S<sub>i</sub> sensitivity of the gene to the transcription factor.
- $D_i$  decay rate of the mRNA.
- ▶ Goal: infer the unobserved activation f(t) from mRNA measurements of multiple target genes.

#### Derivative observations

- > The key to solving this problem are derivative observations.
- Given knowledge about the derivative of a function f we would like to infer its function values:

$$dy = \frac{\partial f(t)}{\partial t}$$

We wish to find the joint probability of function values and function derivatives

$$cov(dy_i, y_j) = \frac{\partial}{\partial t_i} cov(y_i, y_j)$$
$$cov(dy_i, dy_j) = \frac{\partial^2}{\partial t_i \partial t_j} cov(y_i, y_j)$$

 Using these covariance functions we can combine function observations and derivatives as training data in GP regression.

#### Derivative observations

- > The key to solving this problem are derivative observations.
- Given knowledge about the derivative of a function f we would like to infer its function values:

$$dy = \frac{\partial f(t)}{\partial t}$$

We wish to find the joint probability of function values and function derivatives

$$cov(dy_i, y_j) = \frac{\partial}{\partial t_i} cov(y_i, y_j)$$
$$cov(dy_i, dy_j) = \frac{\partial^2}{\partial t_i \partial t_j} cov(y_i, y_j)$$

 Using these covariance functions we can combine function observations and derivatives as training data in GP regression. processes

#### Derivative observations Squared exponential kernel

For the squared exponential kernel we obtain:

$$\begin{aligned} & \operatorname{cov}(y_i, y_j) = k(t_i, t_j) = A^2 e^{-0.5 \frac{(t_i - t_j)^2}{L^2}} \\ & \operatorname{cov}(dy_i, y_j) = -\operatorname{cov}(y_i, y_j) \frac{(t_i - t_j)}{L^2} \\ & \operatorname{cov}(dy_i, dy_j) = \operatorname{cov}(y_i, y_j) \frac{1}{L^2} \left[ \delta_{i,j} - \frac{1}{L^2} (t_i - t_j)^2 \right] \end{aligned}$$

#### Back to the ODE model for gene regulation

$$\frac{\mathrm{d}y_i(t)}{\mathrm{d}t} = B_i + S_i f(t) - D_i y_i(t)$$

An explicit solution of the ODE system can be derived (standard ODE techniques)

$$y_i(t) = \frac{B_i}{D_i} + k_i e^{-D_i t} + S_i e^{-D_i t} \int_0^t f(u) \exp(D_i u) du$$
$$y_i(t) = \frac{B_i}{D_i} + L_i[f](t)$$

• Realizing that  $L_i$  is a linear operator (like taking the derivative), we can again evaluate the covariance between f(t) and  $L_i[f](t)$ .

(日) (同) (三) (三)

### ODE model for gene regulation Inference results

Figure 1: Predicted protein concentration for p53 using a linear response model: (a) squared exponential prior on f; (b) MLP prior on f. Solid line is mean prediction, dashed lines are 95% credibility intervals. The prediction of Barenco *et al.* was pointwise and is shown as crosses.
